

## Results about Euler's path and circuits

### MATH 450 Seminar in Proof

**Definition 1.1: Graph:** A simple graph  $G = (V, E)$  consists of a non-empty finite set  $V(G)$  of elements called vertices (or nodes), and a finite set  $E(G)$  of distinct unordered pairs of distinct elements of  $V(G)$  called edges. We call  $V(G)$  the vertex set and  $E(G)$  the edge set of  $G$ . An edge  $v, w$  is said to join the vertices  $v$  and  $w$ , and is usually abbreviated to  $vw$ .

**Note:** The vertex on  $G$  are referred to as  $V(G)$  and the edges on  $G$  are referred to  $E(G)$ . This is independent of the way we define a graph. Meaning, if we define a graph  $H = (W, Q)$  the set of vertices in  $H$  is referred as  $V(H)$  and the set of edges in  $H$  is referred as  $E(H)$  and not  $W(H)$  and  $Q(H)$  respectively.

**Definition 1.2: Adjacency:** We say that two vertices  $v$  and  $w$  of a graph  $G$  are **adjacent** if there is an edge  $vw$  joining them, and the vertices  $v$  and  $w$  are then incident with such an edge. Similarly, two distinct edges  $e$  and  $f$  are adjacent if they have a vertex in common.

**Definition 1.3: Degree of a Vertex:** The degree of a vertex  $v$  of  $G$  is the number of edges incident with  $v$ , and is written  $\deg(v)$ ; in calculating the degree of  $v$ , we usually make the convention that a loop at  $v$  contributes 2 (rather than 1) to the degree of  $v$ . A vertex of degree 0 is an isolated vertex and a vertex of degree 1 is an end-vertex.

**Note:** A graph is **connected** if it cannot be expressed as the union of two graphs, and disconnected otherwise. Or, in simpler words, if a graph does not have any isolated or end-vertex, then the graph is **connected**.

**Definition 1.4: Subgraph:** A *subgraph* of a graph  $G$  is a graph, each of whose vertices belongs to  $V(G)$  and each of whose edges belongs to  $E(G)$ .

**Definition 1.5: Walk:** Given a graph  $G$ , a walk in  $G$  is a finite sequence of distinct edges of the form  $v_0v_1, v_1v_2, \dots, v_{m-1}v_m$ , also denoted by  $v_0 \rightarrow v_1 \rightarrow v_2 \rightarrow \dots \rightarrow v_m$ , in which any two consecutive edges are adjacent or identical. If  $v_0 = v_m$  then we call the walk a cycle.

**Definition 1.6: Euler Path:** An *Euler Path* on a graph  $G$  is a special *walk* that uses each edge exactly once.

**Definition 1.7: Euler Circuit/Cycle:** An Euler circuit on a graph  $G$  is a Euler Path which starts and ends on the same vertex.

**Definition 1.8: Traversing:** The process of passing through each vertex using the edges joining them in a walk or a path or a cycle or a trail.

**Lemma: Nilay's Lemma (Not really):** If a connected finite graph has every vertex of degree of at least two, then  $G$  has a **cycle**.

*Proof.* Let  $G$  be a connected finite graph. Let  $v$  be a vertex in  $G$  such that  $v$  has at least degree two. Let us construct a walk  $v_0 \rightarrow v_1 \rightarrow v_2 \rightarrow \dots$  such that  $v_1$  be any adjacent vertex to  $v_0$ , and for each  $v_i$   $i > 1$ , we choose  $v_{i+1}$  to be any adjacent vertex to  $v_i$ , except  $v_{i-1}$  (already chosen). We know that such a vertex exists because of our hypothesis that every vertex is of at least degree two. Since  $G$  is finite graph, the

number of vertices it has is finite. Thus, while constructing our walk we will eventually choose a vertex  $v_k$  which has already been chosen and included in the walk. If  $v_k$  is first such vertex that we encounter, then the path that was created from the first occurrence of  $v_k$  to the second one is a *cycle* from  $v_k$  to  $v_k$ .  $\square$

### Results to be proven:

1. (**EULER (1736), HIERHOLZER (1873)**) Any connected graph where the degree of every vertex is even iff it has an Euler circuit.

*Proof.*  $\implies$  Let  $G$  be a connected graph which has Euler circuit  $E$ . When traversing  $E$ , when we come across any vertex  $v$  through an edge  $e_v(1)$ , we know by definition there is another edge  $e_v(2)$  that is connected to  $v$ . Thus making every vertex in  $G$  at least degree two. Thus making every vertex in  $G$  of even degree.

$\Leftarrow$  Let every vertex in a connected graph  $G$  have an even degree. Let there be only two vertices in  $G$  and each vertex is of degree two (making them even degree). Then since  $G$  is connected, there are no isolated vertex in  $G$ . Furthermore, those two vertices share the two edges between them. Therefore, if we construct a walk at either of the vertex we will end at the same vertex where we started, and not repeating the edge that we passed through. Thus making the walk a Euler Circuit.

Now, let  $G$  be connected graph with more than two vertices. From the lemma we know that there exists a cycle in  $G$ . If a cycle includes all the edges in  $G$  then we are done. Let's say it does not. Then there exists a cycle  $C$  in  $G$  which does not include all the vertices. Now, let us remove all the edges from  $G$  that are in  $C$  and obtain newly made sub-graph  $H$ , made by the remaining edges in  $G$ , by our hypothesis all the vertices in  $H$  are still even. We know that because the common the vertices in  $H$  are the same vertices in  $G$ , and since each vertex in  $G$  are of even degree, vertices in  $H$  are also of even degree. Thus, by  $H$  contains a cycle. Let us choose a common vertex  $v$  in  $C$  and  $H$ . We know this is possible because connectedness of  $G$ .

Now since  $v$  still has an even degree we produce a cycle  $C'$  in  $H$  that starts and ends at  $v$ . Now the cycle formed by combining  $C'$  in  $H$  and  $C$  in  $G$  forms a new cycle in  $G$ , that starts and ends at  $v$  and containing more edges than in  $C$ .

We continue the above process recursively for each sub-graph in  $G$  until all the vertices in  $G$  are traversed. The final cycle starting from such a vertex  $v$  will include all the edges in  $G$  and will be the union of all the cycles that we created recursively in  $G$  and it's sub-graphs, thus making an Euler circuit in  $G$ .

They say a picture speaks a thousand words, below we try to illustrate what an Euler Circuit will look like on a graph where all the vertex have an even degree.  $\square$

Figure 1: A Euler Circuit.

2. If there are exactly two vertices  $a$  and  $b$  of odd degree, there is an Euler path on the graph from  $a$  to  $b$ . (Existence Proof)

*Proof.* Let  $G$  be a graph with Euler circuit. Thus, we know that every vertex in  $G$  has an even degree from the theorem stated above. Now let us add one vertex say  $b \notin V(G)$  and an edge  $e_{ba} \notin E(G)$  to a vertex  $a \in V(G)$ . Note that before adding the edge from  $e_{ba}$  to  $a$ ,  $a \in V(G)$  had an even degree. We start our path from  $b$ , and since it has only one edge  $e_{ba}$  connecting to  $a$ . We know that  $a \in V(G)$  and since  $G$  has a Euler Circuit, we know that we can construct a cycle that starts and ends at  $a \in G$ . We cannot use the edge  $e_{ba}$  to go back to  $b$  as we have already included in our path. Therefore, the path will end at  $a$ . Thus, we know have a graph  $G' = (V(G) + b, E(G) + e_{ba})$ , where  $a$  and  $b$  are two vertices in  $G'$  that are of odd degree and an Euler Path from  $b$  to  $a$ .
